TDA8547
2 × 1 W BTL audio amplifier with output channel switching

Preliminary specification
File under Integrated Circuits, IC01

1997 Oct 07
2 × 1 W BTL audio amplifier with output channel switching

**FEATURES**
- Selection between output channels
- Flexibility in use
- Few external components
- Low saturation voltage of output stage
- Gain can be fixed with external resistors
- Standby mode controlled by CMOS compatible levels
- Low standby current
- No switch-on/switch-off plops
- High supply voltage ripple rejection
- Protected against electrostatic discharge
- Outputs short-circuit safe to ground, \( V_{CC} \) and across the load
- Thermally protected.

**APPLICATIONS**
- Telecommunication equipment
- Portable consumer products
- Personal computers
- Motor-driver (servo).

**GENERAL DESCRIPTION**

The TDA8547(T) is a two channel audio power amplifier for an output power of \( 2 \times 1 \) W with an \( 8 \) \( \Omega \) load at a 5 V supply. The circuit contains two BTL amplifiers with a complementary PNP-NPN output stage and standby/mute logic. The operating condition of all channels of the device (standby, mute or on) is externally controlled by the MODE pin. With the SELECT pin one of the output channels can be switched in the standby condition. This feature can be used for loudspeaker selection and also reduces the quiescent current consumption. The TDA8547T comes in a SO16 package and the TDA8547 in a DIP16 package.

FUNCTIONAL DESCRIPTION

The TDA8547(T) is a 2 × 1 W BTL audio power amplifier capable of delivering 2 × 1 W output power to an 8 Ω load at THD = 10% using a 5 V power supply. Using the MODE pin the device can be switched to standby and mute condition. The device is protected by an internal thermal shutdown protection mechanism. The gain can be set within a range from 6 to 30 dB by external feedback resistors.

Power amplifier

The power amplifier is a Bridge-Tied Load (BTL) amplifier with a complementary PNP-NPN output stage. The voltage loss on the positive supply line is the saturation voltage of a PNP power transistor, on the negative side the saturation voltage of a NPN power transistor. The total voltage loss is <1 V and with a 5 V supply voltage and an 8 Ω loudspeaker an output power of 1 W can be delivered.

MODE pin

The whole device (both channels) is in the standby mode (with a very low current consumption) if the voltage at the MODE pin is >(VCC − 0.5 V), or if this pin is floating. At a MODE voltage level of less than 0.5 V the amplifier is fully operational. In the range between 1.5 V and VCC − 1.5 V the amplifier is in mute condition. The mute condition is useful to suppress plop noise at the output caused by charging of the input capacitor.

SELECT pin

If the voltage at the SELECT pin is in the range between 1.5 V and VCC − 1.5 V, or if it is kept floating, then both channels can be operational. If the SELECT pin is set to a LOW voltage or grounded, then only channel 2 can operate and the power amplifier of channel 1 will be in the standby mode. In this case only the loudspeaker at channel 2 can operate and the loudspeaker at channel 1 will be switched off. If the SELECT pin is set to a HIGH level or connected to VCC, then only channel 1 can
operate and the power amplifier of channel 2 will be in the standby mode. In this case only the loudspeaker at channel 1 can operate and the loudspeaker at channel 2 will be switched off. Setting the SELECT pin to a LOW or a HIGH voltage results in a reduction of quiescent current consumption by a factor of approximately 2.

Switching with the SELECT pin during operating is not plop-free, because the input capacitor of the channel which is coming out of standby needs to be charged first.

For plop-free channel selecting the device has first to be set in mute condition with the MODE pin (between 1.5 V and $V_{CC} - 1.5$ V), then set the SELECT pin to the new level, after a delay set the MODE pin to a LOW level. The delay needed depends on the values of the input capacitor and the feedback resistors. Time needed is approx. $10 \times C_1 \times (R_1 + R_2)$, so approximately 0.6 s. for the values in Fig.4.

### Notes
1. HIGH = $V_{pin} > V_{CC} - 0.5$ V.
2. NC = not connected or floating.
3. X = don’t care.
4. HVP = $1.5$ V < $V_{pin} < V_{CC} - 1.5$ V.
5. LOW = $V_{pin} < 0.5$ V.

### LIMITING VALUES
In accordance with the Absolute Maximum Rating System (IEC 134).

### QUALITY SPECIFICATION
In accordance with “SNW-FQ-611-E”. The number of the quality specification can be found in the “Quality Reference Handbook”. The handbook can be ordered using the code 9397 750 00192.

**Notes**

1. Measured with $R_L = \infty$. With a load connected at the outputs the quiescent current will increase, the maximum of this increase being equal to the DC output offset voltage divided by $R_L$.

2. The DC output voltage with respect to ground is approximately $0.5V_{CC}$.

Notes

1. Gain of the amplifier is \( 2 \times \frac{R_2}{R_1} \) in BTL application circuit Fig.4.
2. The noise output voltage is measured at the output in a frequency range from 20 Hz to 20 kHz (unweighted), with a source impedance of \( R_S = 0 \\Omega \) at the input.
3. Supply voltage ripple rejection is measured at the output, with a source impedance of \( R_S = 0 \\Omega \) at the input. The ripple voltage is a sine wave with a frequency of 1 kHz and an amplitude of 100 mV (RMS), which is applied to the positive supply rail.
4. Supply voltage ripple rejection is measured at the output, with a source impedance of \( R_S = 0 \\Omega \) at the input. The ripple voltage is a sine wave with a frequency between 100 Hz and 20 kHz and an amplitude of 100 mV (RMS), which is applied to the positive supply rail.
5. Output voltage in mute position is measured with a 1 V (RMS) input voltage in a bandwidth of 20 Hz to 20 kHz, so including noise.
6. Channel separation is measured at the output with a source impedance of \( R_S = 0 \\Omega \) at the input and a frequency of 1 kHz. The output power in the operating channel is set to 0.5 W.
TEST AND APPLICATION INFORMATION

Test conditions

Because the application can be either Bridge-Tied Load (BTL) or Single-Ended (SE), the curves of each application are shown separately.

The thermal resistance = 55 K/W for the DIP16; the maximum sine wave power dissipation for T_{amb} = 25 °C is: \[ \frac{150 - 25}{55} = 2.3 \text{ W} \]

For T_{amb} = 60 °C the maximum total power dissipation is:
\[ \frac{150 - 60}{55} = 1.7 \text{ W} \]

BTL application

T_{amb} = 25 °C if not specially mentioned, V_{CC} = 5 V, f = 1 kHz, R_{L} = 8 Ω, G_{V} = 20 dB, audio band-pass 22 Hz to 22 kHz.

The BTL application circuit is illustrated in Fig.4.

The quiescent current has been measured without any load impedance and both channels driven. When one channel is active the quiescent current will be halved.

The total harmonic distortion as a function of frequency was measured using a low-pass filter of 80 kHz.

The value of capacitor C3 influences the behaviour of the SVRR at low frequencies: increasing the value of C3 increases the performance of the SVRR.

The figure of the MODE voltage (V_{MODE}) as a function of the supply voltage shows three areas: operating, mute and standby. It shows, that the DC-switching levels of the mute and standby respectively depend on the supply voltage level. The figure of the SELECT voltage (V_{SELECT}) as a function of the supply voltage shows the voltage levels for switching the channels in the active, mute or standby mode.

SE application

T_{amb} = 25 °C if not specially mentioned, V_{CC} = 7.5 V, f = 1 kHz, R_{L} = 4 Ω, G_{V} = 20 dB, audio band-pass 22 Hz to 22 kHz.

The SE application circuit is illustrated in Fig.16.

Increasing the value of electrolytic capacitor C3 will result in a better channel separation. Because the positive output is not designed for high output current \((2 \times I_{o})\) at low load impedance \((\leq 16 \Omega)\), the SE application with output capacitors connected to ground is advised.

The capacitor value of C6/C7 in combination with the load impedance determines the low frequency behaviour.

The THD as a function of frequency was measured using a low-pass filter of 80 kHz. The value of capacitor C3 influences the behaviour of the SVRR at low frequencies: increasing the value of C3 increases the performance of the SVRR.

General remark

The frequency characteristic can be adapted by connecting a small capacitor across the feedback resistor. To improve the immunity to HF radiation in radio circuit applications, a small capacitor can be connected in parallel with the feedback resistor \((56 \text{ k}\Omega)\); this creates a low-pass filter.

SOLDERING

Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our “IC Package Databook” (order code 9398 652 90011).

DIP

SOLDERING BY DIPPING OR BY WAVE

The maximum permissible temperature of the solder is 260 °C; solder at this temperature must not be in contact with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature (Tstg max). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

REPAIRING SOLDERED JOINTS

Apply a low voltage soldering iron (less than 24 V) to the lead(s) of the package, below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than 300 °C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and 400 °C, contact may be up to 5 seconds.

SO

REFLOW SOLDERING

Reflow soldering techniques are suitable for all SO packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at 45 °C.

WAVE SOLDERING

Wave soldering techniques can be used for all SO packages if the following conditions are observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow.
- The package footprint must incorporate solder thieves at the downstream end.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

REPAIRING SOLDERED JOINTS

Fix the component by first soldering two diagonally-opposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.

Limiting values

Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.

Application information

Where application information is given, it is advisory and does not form part of the specification.

LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
